Simulations

Parameters

• Number of Ls: 50

• Draws per L: 50

• Number of Units: 100

• Number of Control Units: 98

• Number of Times: 200

• Number of pre-treatment Times: 198

• Rank of L: 10

• Autocorrelation Parameter: 0

• True Effect Size: 10

• Error Type: gaussian

• Error Variance (if Gaussian error): 16

• Degrees of freedom (if t-error): 5

• Exchangable: FALSE

• Penalized: TRUE

• Rank Estimation Method: threshold

• Scaling for L: 5

Simulation Description

In this simulation we sample 50 signal matricies $L \in \mathbb{R}^{100 \times 200}$ of rank 10, and for each L we sample 50 Ys such that for each $Y E(Y_{ij}) = L_{ij} + \tau W_{ij}$ where W is known, and $\tau = 10$ (in the case of the t-distribution, we ensure the median of each cell is $L_{ij} + \tau W_{ij}$). We generate L so that the rows and columns are not exchangable, and we estimate the weights in SDID using penalized regressions. For estimating the rank of L we are using a threshold method. From each corresponding pair of (L, Y) an estimate of τ is generated via method i, which we call $\hat{\tau}_{(L,Y),i}$. To evaluate the performance of method i we calculate the following mse:

$$mse_i = \sqrt{\frac{1}{2500} \sum_{(L,Y)} (\hat{\tau}_{(L,Y),i} - \tau)^2}$$

Matrix Bias vs Reduction in Variance due to Averaging

For more general designs of W (like the block design scheme considered here) we allow a block in the bottom right hand corner of W to be non-zero. When implementing our method, we have two competing effects on estimation:

- The bias that's introduced by making more of the Y_{ij} s zero.
- The help we get with estimating τ by being able to average over cells (because we assume tau) is the same for all units and times.

It would appear that accurracy increases for estimating τ to a point, and then decreases when the bias introduced by replacement of cells with 0 in Y becomes too great.
